Why linear programming?

1. Vast range of applications
   - Resource allocation
   - Production planning
   - Military strategy forming
   - Graph theoretic problems
   - Error correction
   - ...

2. Establish the existence of polynomial-time (efficient) algorithms

3. Guide the design of approximation algorithms for computationally hard problems *(coming up in the next two weeks)*

4. Duality allows to unify abstract views of seemingly unrelated results and is useful in algorithm design
Today

1. Introduction

2. The structure of a linear program

3. Duality

4. Examples

5. Taking the dual of an LP
An introductory example: profit maximization

A boutique chocolatier has two products:

- an assortment of chocolates
- an assortment of truffles

Their profit is

1. $1 per box of chocolates
2. $6 per box of truffles

They can produce a total of at most 400 boxes per day. The daily demand for these products is limited

1. at most 200 boxes of chocolates per day
2. at most 300 boxes of truffles per day

What are the optimal levels of production?
1. Let $x_1$ be the number of boxes of chocolates and $x_2$ the number of boxes of truffles produced daily.

2. **Objective:** maximize $x_1 + 6x_2$

3. **Constraints:** $x_1 \geq 0$, $x_2 \geq 0$ (*special constraints*);
   $x_1 \leq 200$, $x_2 \leq 300$, $x_1 + x_2 \leq 400$

**Linear program** for chocolatier’s profit

\[
\begin{align*}
\text{max} & \quad x_1 + 6x_2 \\
\text{subject to} & \quad x_1 \leq 200 \\
& \quad x_2 \leq 300 \\
& \quad x_1 + x_2 \leq 400
\end{align*}
\]
The general problem

**Input**

1. a set of **variables**
2. a set of **linear constraints** on the variables (equalities or inequalities)
3. a **linear objective function** to maximize (or minimize)

**Output**

- an assignment of real values to the variables such that
  1. the constraints are satisfied;
  2. the objective function is maximized (or minimized)

*A more succinct linear algebraic formulation of a linear program will appear in a later slide.*
Solution: an assignment of real values to the variables

Feasible solution: a solution that satisfies all the constraints (including the special ones)

Feasible region: the set of all feasible solutions

Optimal solution: a feasible solution that maximizes (minimizes) the objective function if the LP is a maximization (minimization) LP

Cost or value of a solution: the value of the objective function for this solution

Optimal value of the LP: the value of an optimal solution
The geometry of the solution: feasible region

- \( x_1 + x_2 = 400 \)
- \( x_2 = 300 \)
- \( x_1 = 200 \)
The geometry of the solution: objective function

Optimum point
Profit= $1900
The set of all feasible solutions is the set of points in the \((x_1, x_2)\) plane that satisfy all five constraints.

A linear equation in \(x_1\) and \(x_2\) defines a line on that plane.

A linear inequality defines a half-space on that plane (one side of the line).

The set of all feasible solutions is the intersection of the five half-spaces.

**Goal:** Find the point in this polygon that maximizes the objective function (the profit).
Fact 1. The optimum is achieved at a vertex of the feasible region.

Exceptions

1. The linear program is infeasible
   - e.g., $x \leq 1$, $x \geq 2$

2. The optimum value is unbounded

\[
\max_{x_1 \geq 0, x_2 \geq 0} x_1 + x_2
\]
For more information on simplex, take, e.g., Optimization I (IEOR 6613).
Some history on LP solvers

- Simplex method [Dantzig1947]
  - fast in practice
  - exponential worst case performance
- Ellipsoid method [Khachiyan1979]
  - provably polynomial-time algorithm
  - slow in practice
- Interior-point method [Karmarkar]
  - polynomial-time algorithm
  - fast in practice
- Interior-point methods is a field of active research
Today

1  Introduction

2  The structure of a linear program

3  Duality

4  Examples

5  Taking the dual of an LP
An alternative proof that $1900$ is optimal

Recall the LP from slide 7.

\[
\begin{align*}
& \text{max} \quad x_1 + 6x_2 \\
& \text{subject to} \quad x_1 \leq 200 \\
& \quad x_2 \leq 300 \\
& \quad x_1 + x_2 \leq 400
\end{align*}
\]
Using the constraints to upper bound the objective

- Multiply the first inequality by 0
- Multiply the second inequality by 5
- Multiply the third inequality by 1
- Add the new inequalities; then

\[ x_1 + 6x_2 \leq 1900 \]

\[ \Rightarrow \] the objective function cannot exceed 1900!
\[ \Rightarrow \] thus we indeed found the optimal solution

*Where did we get the multipliers 0, 5 and 1?*
The constraints themselves can help us derive an upper bound.

<table>
<thead>
<tr>
<th>Multiplier</th>
<th>Inequality</th>
</tr>
</thead>
<tbody>
<tr>
<td>$y_1$</td>
<td>$x_1 \leq 200$</td>
</tr>
<tr>
<td>$y_2$</td>
<td>$x_2 \leq 300$</td>
</tr>
<tr>
<td>$y_3$</td>
<td>$x_1 + x_2 \leq 400$</td>
</tr>
</tbody>
</table>

- Multipliers $y_i$ must be non-negative (*why?*)

Add the multiplied inequalities together:

$$y_1 x_1 + y_2 x_2 + y_3 (x_1 + x_2) \leq 200 y_1 + 300 y_2 + 400 y_3$$
An upper bound for the objective

We want to upper bound the original objective

$$1x_1 + 6x_2$$

using the linear combination

$$y_1x_1 + y_2x_2 + y_3(x_1 + x_2) \leq 200y_1 + 300y_2 + 400y_3$$

$$\Rightarrow (y_1 + y_3)x_1 + (y_2 + y_3)x_2 \leq 200y_1 + 300y_2 + 400y_3 \quad (1)$$
We want to upper bound the original objective

\[ 1x_1 + 6x_2 \]

using the linear combination

\[ y_1x_1 + y_2x_2 + y_3(x_1 + x_2) \leq 200y_1 + 300y_2 + 400y_3 \]

\[ \Rightarrow (y_1 + y_3)x_1 + (y_2 + y_3)x_2 \leq 200y_1 + 300y_2 + 400y_3 \quad (1) \]

Since \( x_1, x_2 \geq 0 \), if we constrain \( y_1 + y_3 \geq 1 \) and \( y_2 + y_3 \geq 6 \), then the right-hand side in (1) is an upper bound for our objective.
The dual LP

▶ What is the \textbf{\textit{best possible}} upper bound for our objective?

Minimize equation (1) subject to constraints on \(y_1, y_2, y_3\).

▶ This is yet another LP!

\[
\begin{align*}
\text{min} & \quad 200y_1 + 300y_2 + 400y_3 \\
\text{subject to} & \quad y_1 + y_3 \geq 1 \\
& \quad y_2 + y_3 \geq 6
\end{align*}
\]

This new LP is called the \textbf{\textit{dual}} of the original, which is called the \textbf{\textit{primal}}.
Weak duality

- By construction, any feasible solution for the dual LP is an upper bound on the original primal LP.
- Let $V_P$ be the optimal objective value for the primal (a maximization)
- Let $V_D$ be the optimal objective value for the dual (a minimization)

Theorem 2 (Weak Duality).

$$V_P \leq V_D$$

The upper bounding strategy can also be used for more general kinds of optimization problems, and weak duality again holds.
Suppose we found a pair of primal and dual feasible values that are equal.

Then they must both be optimal.

E.g., in our chocolatier’s profit maximization problem

- \((x_1, x_2) = (100, 300)\) is a feasible solution for the primal LP
- \((y_1, y_2, y_3) = (0, 5, 1)\) is a feasible solution for the dual LP
- they have the same value of 1900.

Thus these solutions certify each other’s optimality.

Amazingly, this is always possible for LPs with bounded optima.

**Theorem 3 (Strong Duality).**

\[ V_P = V_D \]
Strong duality consequences

- We can alternatively solve the dual to find the optimal objective value.
- An optimal dual solution can be used to derive an optimal primal solution (complementary slackness).
- The dual may have structure making it easier to solve at scale (e.g., via parallel optimization).
Today

1 Introduction

2 The structure of a linear program

3 Duality

4 Examples

5 Taking the dual of an LP
Suppose that the chocolatier introduces a third product, *seasonal* truffles, such that

- *seasonal* truffles yield a profit of $13 per box
- ≤ 100 boxes of *seasonal* truffles may be produced.

*What are the new optimal levels of production?*

*What if we add a fourth line of production? A hundred-th?*

- High-dimensional problem
- Simplex still works!
LP for more products

\[ \max_{x_1 \geq 0, x_2 \geq 0, x_3 \geq 0} \quad x_1 + 6x_2 + 13x_3 \]

subject to

\[ x_1 \leq 200 \]
\[ x_2 \leq 300 \]
\[ x_3 \leq 100 \]
\[ x_1 + x_2 + x_3 \leq 400 \]
Production planning for a carpet company

- The company has 30 employees.
- Each employee makes 20 carpets per month.
- Monthly employee salary is $2000.
- Initially, no surplus of carpets.

Your data shows that carpet demand is extremely seasonal: monthly demand $d_i$ ranges from 440 to 920. Fluctuations in demand may be handled as follows

1. Overtime
   - they are paid 80% more than regular workers
   - workers can put in at most 30% overtime.

2. Hiring and firing
   - these cost $320 and $400 respectively per worker

3. Storing surplus production
   - costs $8 per month
   - no stored carpets at the end of the year

Goal: minimize yearly expenses for company
Variables for carpet company production planning

- \( w_i \) = number of workers during \( i \)-th month; \( w_0 = 30 \)
- \( h_i, f_i \) = number of workers hired and fired, respectively, at beginning of month \( i \)
- \( x_i \) = number of carpets made during \( i \)-th month
- \( o_i \) = number of carpets made by overtime in \( i \)-th month
- \( s_i \) = number of carpets stored at end of month \( i \); \( s_0 = 0 \)
LP for carpet company production planning

Constraints (one constraint for every month $1 \leq i \leq 12$)

- $w_i, h_i, f_i, x_i, o_i, s_i \geq 0$
- $x_i = 20w_i + o_i$
- $w_i = w_{i-1} + h_i - f_i$
- $s_i = s_{i-1} + x_i - d_i$
- $o_i \leq 6w_i$

Objective:

$$
\min \ 2000 \sum_{i} w_i + 320 \sum_{i} h_i + 400 \sum_{i} f_i + 8 \sum_{i} s_i + 180 \sum_{i} o_i
$$

What if solution is not integral?
Today

1. Introduction

2. The structure of a linear program

3. Duality

4. Examples

5. Taking the dual of an LP
We may rewrite any LP as follows (*think about it!*).

1. It is either a maximization or a minimization
2. All constraints are inequalities in the same direction
3. All variables are non-negative

This results in an LP of the following form

$$\max_{\mathbf{x} \geq 0} \quad \mathbf{c}^T \mathbf{x}$$

subject to \( \mathbf{A} \mathbf{x} \leq \mathbf{b} \)
Then the dual is given as follows *(prove this!)*.

\[
\min_{y \geq 0} \ b^T y \\
\text{subject to} \ A^T y \geq c
\]

By construction, we know that the any feasible solution to the primal is upper bounded by any feasible solution to the dual *(weak duality)*. Hence

\[
c^T x \leq b^T y
\]

What if the primal is unbounded?
What if the dual is unbounded?
Feasibility vs Optimality

Finding a feasible solution of a linear program is generally computationally as difficult as finding an optimal solution.

For example, consider the primal in slide 32. Any feasible solution to the following LP (restricted to \( x \)) is an optimal solution to the primal.

\[
\begin{align*}
\max_{x \geq 0, y \geq 0} & \quad c^T x \\
\text{subject to} & \quad A x \leq b \\
& \quad A^T y \geq c \\
& \quad c^T x \geq b^T y
\end{align*}
\]
Note that \( b \in \mathbb{R}^m \), \( c \in \mathbb{R}^n \), \( A \in \mathbb{R}^{m \times n} \)
